Quick Reference Guide

SAS2Flash Utility

This document explains how to use the SAS2Flash Utility and all of its commands.

1.0 Introduction

The SAS2Flash Utility enables you to flash the Fusion-MPT™ firmware and the OptionROM image on LSI SAS2 controllers and host bus adapters (HBAs). You can also use this powerful utility to perform tasks such as displaying HBA information, programming SAS addresses, testing BIOS versions, and displaying the contents of the Ethernet page.

This document is intended for the following audiences:

- Engineers who work in manufacturing environments
- System engineers, test engineers, and firmware engineers
- OEMs, LSI employees, and end users

This document provides the command line option syntax and functionality of all SAS2Flash Utility commands. It also explains a few limitations of different platform builds of the SAS2Flash Utility (see Section 7.0, Operating System Limitations, on page 22).

CAUTION: Before you use the SAS2Flash Utility commands, be sure you understand how they operate. Some of the commands, such as the one that erases regions of the controller, are potentially destructive if they are not used correctly.

2.0 Hardware and Software Compatibility

2.1 LSI SAS2 Controllers and HBAs

The SAS2Flash Utility is compatible with the following hardware and software.

The SAS2Flash Utility supports all LSI SAS2 Fusion-MPT architecture controllers and the HBAs based on these controllers, implemented to message passing interface (MPI) v2.0. Currently, the SAS2Flash Utility supports the following controller models:

- LSISAS2004
- LSISAS2008
- LSISAS2108
- LSISAS2116
- LSISAS2208
- LSISAS2308

MPI defines the host interface used by all LSI common architecture chipsets and allows the quick development of host-based drivers and applications.
2.2 Hardware Platforms

The SAS2 Flash Utility is compatible with the following hardware platforms:

- Intel® EM64T/Advanced Micro Devices® AMD64®
- Intel IA-64
- Intel x86 (i386/i486 processor family) or compatible
- Sun® SPARC® V9
- IBM® PowerPC® 64

2.3 Operating Systems

The SAS2 Flash Utility is compatible with the following operating systems:

- Red Hat® Enterprise Linux® (RHEL) 4, RHEL 5
- SUSE® Linux Enterprise Server (SLES) 9, and SLES 10
- Microsoft® MS-DOS® 6.22
- FreeDOS™ 1.0
- WinPE 1.x (Server 2003/XP), WinPE 2.0 (Vista), WinPE 2.1 (Server 2008)
- Unified Extensible Firmware Interface (UEFI) version 2.1
- Sun OpenSolaris™ build 113 and later
- FreeBSD™ 7.3

2.4 OS Architecture

The SAS2 Flash Utility is compatible with the following operating system architectures:

- Windows/WinPE – x86, x64 (AMD64), IA64
- UEFI – UEFI Byte Code (UEBC)
- Linux® – x86 compatible, PPC64
- Solaris™ – x86 or compatible, SPARC
- FreeBSD – x86 or compatible

2.5 Other Software

The SAS2 Flash Utility is compatible with the following software and firmware:

- PCI firmware - PCI 2.X, PCI 3.0
- MPT firmware - MPI 2.0.x
- DOS – Support for BIOS32 services in System BIOS (for DOS version)
- UEFI firmware 2.1 (for UEFI version)
- Windows driver v2.00.00.19 or later (for Windows version)
- Linux driver v00.255.04 (2.6 kernel) or later (for Linux version)
- Solaris driver v00.00.15.00 or later (for Solaris version)
- FreeBSD driver version 2.00.00.01 or later (for FreeBSD version)

**NOTE:** The SAS2 Flash Utility requires an amount of memory equal to the sum of the flash memory size of the SAS2 controller, plus 0.5 MB. For most controllers, the requirement is 2.5 MB.

**NOTE:** The SAS2 Flash Utility supports the MPI V2.0.x firmware interface. It does not support any earlier versions of MPI.
3.0 Starting the Utility

Use the following commands to start the SAS2Flash Utility:

- **DOS:** `sas2flsh`
- **Other operating systems:** `sas2flash`

4.0 Modes of Operation

The SAS2Flash Utility supports the following modes of operation.

- **Command Line Mode**
  Most command line parameters place the SAS2Flash Utility in command line mode. This mode receives most of its input from the command line parameters. It attempts to run without prompting you for input, unless it needs input to complete a command.

  If you invoke the SAS2Flash Utility in silent mode (see Section 5.4.29, Silent Switch, on page 19), the utility does not prompt you for input. If it needs input, it logs an error that indicates the required input.

- **User Interface Mode**
  The SAS2Flash Utility uses a standard 80x25 text mode interface to give you an overview of an operation. The user interface contains advanced mode and standard mode, which you select using the command line.

- **Command File Mode**
  The SAS2Flash Utility supports a command file, because command lines can be very long and many operating systems place a limit on their length. A command file, which is an ASCII text file, contains the parameters that you would otherwise enter on the command line. When you provide a command file, the utility does not use other command line parameters.

5.0 Commands

This section describes the commands that the SAS2Flash Utility supports.

5.1 Command Line Format

The command line begins with `sas2flash` (or `sas2flsh` in DOS), followed by one or more switches that are separated by spaces, followed by a filename or other arguments required by a switch.

Example:

```
sas2flash -o -f filename
```

The first switch, `-o`, does not take a parameter. The second option, `-f`, takes a filename as a parameter. Spaces are required because there can be multiple command line options that start with the same letters.
5.2 Command Line Ordering

The structure of the command line determines the order in which the SAS2Flash Utility runs the commands. To determine the order of the commands, the utility follows this two-step process.

1. All commands have a preassigned order level based on the following six categories. The SAS2Flash Utility sorts the options according to this order and runs the commands in that sequence.
   a. Order 0 – Flags
   b. Order 1 – All controller commands
   c. Order 2 – Choose adapter
   d. Order 3 – BIOS and firmware flash
   e. Order 4 – Program and test
   f. Order 5 – Display and list

2. Within each order level, the SAS2Flash Utility runs the commands in the sequence in which they appear on the command line, from left to right, with the following exceptions.
   — Order 0 commands are reserved for the command file, which is run separately and cannot be run simultaneously with other commands.
   — Order 2 commands (for example, the command to flash firmware on controllers), cannot run simultaneously with other commands. After running Order 2 commands, the SAS2Flash Utility exits and reports all other commands as not run. If there are no Order 2 commands, the SAS2Flash Utility proceeds to Order 3 and so on, and then runs all commands.

5.3 Command Line Rules

Follow these syntax rules for constructing command lines:

- If a command line option takes a value, use a space to separate the option and the value.
- File names and paths must conform to the syntax rules of the operating system. If the operating system allows spaces in file names, enclose the file name and the path within double quotation marks.
- The SAS2Flash Utility does not support duplicate command line options. If you use duplicate options, the command fails and the utility returns an error message.
- Certain commands support duplicate options, which are mentioned in those command descriptions.
## 5.4 Command Line Parameters

The following table lists the command line parameters of the SAS2Flash Utility. The sections following the table explain the syntax and functionality for each command.

<table>
<thead>
<tr>
<th>Command</th>
<th>Parameter</th>
<th>Order</th>
<th>Advanced Command</th>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advanced Command Mode Switch</td>
<td>-o</td>

<td>Reset all controllers.</td>
</tr>
<tr>
<td>Scan Character Flag</td>
<td>-scanchar</td>
<td>5</td>
<td>Y</td>
<td>string1</td>
<td>Look for character in string1 as the first character when scanning a SAS address.</td>
</tr>
</tbody>
</table>
5.4.1 Advanced Command Mode Switch

The advanced command mode switch enables the SAS2Flash Utility commands that have a Y in the Advanced Command column in the preceding table. If you do not use the –o advanced mode switch preceding these commands on the command line, the SAS2Flash Utility rejects the commands as unrecognized.

Advanced commands are intended for system engineers, test engineers, firmware engineers, and engineers who work in a manufacturing environment. LSI advises that you use advanced commands with great caution.

Syntax:

sas2flash -o

5.4.2 BIOS All

Use the BIOS All command to update the BIOS on all supported controllers. The command only allows updates to a later version of the BIOS image. It does not allow downgrading in a version. The SAS2Flash Utility performs the following steps during the upgrade process:

1. Open the specified file.
2. Determine if the file is a valid BIOS image.

The image validity check includes a basic check for a valid PCI ROM header and a checksum of the core BIOS image.

</tr>
<tr>
<td>Upload NVDATA</td>
<td>-unvdata</td>
<td>5</td>
<td>Y</td>
<td>filename1</td>
<td>Upload the NVDATA to filename1.</td>
</tr>
</tbody>
</table>

   The safety checks ensure that the provided BIOS supports the specified controller family within the limits of the ability of the program. If any of the safety checks fail, the utility skips the controller and continues the process with the next supported controller.

4. If the BIOS download operation succeeds, upload the BIOS image and compare it to the image that was downloaded. If the comparison fails, log a failure.

5. If the BIOS image downloads successfully, attempt to update the BIOS version in VPD.

   The utility checks the VPD information in Manufacturing Page 1 to determine if valid VPD data is available. If so, and if the VPD data has a keyword to hold a BIOS version of the appropriate type (x86 BIOS, FCODE, or UEFI BSD), the utility updates the version string with the version of the newly downloaded BIOS image.

**Syntax:**

```
sas2flash -biosall mptsas.rom
```

### 5.4.3 BIOS Update

Use the BIOS Update command to download a new x86 BIOS image, FCODE, or UEFI boot services driver (BSD). The SAS2Flash Utility performs the following steps during the upgrade process:

1. Open the specified file.
2. Determine if the file is a valid BIOS image.

   The image validity check includes a basic check for a valid PCI ROM header and a checksum of the core BIOS image.
3. Perform a series of safety checks on the controller.

   The safety checks ensure that the provided BIOS supports the specified controller family within the limits of the ability of the program. If any of the safety checks fails, the utility generates a failure report.
4. Update the controller if the file passes all of the checks.

   The BIOS update command supports the duplicate command line option, allowing you to flash x86 BIOS, FCODE, and UEFI BSD in a single command line invocation.

   The SAS2Flash Utility performs a read, modify, and write operation on the BIOS region of the flash. The utility reads the BIOS region, finds the type of image being updated (x86 BIOS, FCODE, or UEFI BSD) in the block, and replaces it with the new image. The utility writes the modified image to the boot region in the flash.

   If the BIOS image downloads successfully, the SAS2Flash Utility uploads the BIOS image and compares it with the downloaded image. If the comparison fails, it logs a failure.

**Syntax:**

```
sas2flash -b mptsas.rom
```
5.4.4 Controller Address Flag
Use the Controller Address flag to indicate the PCI address of the controller on which you want the SAS2Flash Utility to operate. The address is specified as the bus, device, and function number, based on the current mapping of the PCI bus. Multidomain PCI addressing is supported if the operating system supports it. Multidomain PCI addressing uses a PCI segment, bus, device, and function number, as shown in the second of the following syntax examples.

Syntax:
```
sas2flash -cpci 5:3:0
sas2flash -cpci 1:3:2:0
```

5.4.5 Controller Number Flag
Use the Controller Number flag to make the SAS2Flash Utility operate on a specified controller. The controller number, which is the index of the controller, is arbitrary because it is based on the order in which the controllers in the system were discovered. The number is a 1-based index, so the number 1 is assigned to the first controller that is found. Specify the controller number as a hexadecimal value.

Syntax:
```
sas2flash -c 1
```

5.4.6 Command File Directive
Use the Command File directive to specify a command file for execution. When you specify a command file option on the command line, in any order, the SAS2Flash Utility ignores all other command line parameters. Carriage return and line feed characters in the command file are ignored.

Syntax:
```
sas2flash @command.txt
```

The command file contains command line items, such as the ones shown in the following example:
```
-c 2
-b mptsas2.rom
-f ir1068.fw
-reset
```

5.4.7 Debug Switch
Use the Debug switch to enable debug data in the tool that is output to the screen, along with normal output messages. Alternatively, you can direct the debug output to a log file. The debug flag is helpful during the debugging process and can be used together with one or more commands.

Syntax:
```
sas2flash -debug
```

5.4.8 Display Version
Use the Display Version command to display the LSI banner and the SAS2Flash Utility version.

Syntax:
```
sas2flash -ver
```
5.4.9 Download Complete

Flash

Use the Download Complete Flash command to download the complete flash image on the controller. The command takes two files as arguments.

- *Filename1* is the valid complete flash image that must be flashed on the controller.
- *Filename2* is a valid firmware file that the SAS2Flash Utility must use to flash *Filename1* on the controller.

The SAS2Flash Utility performs minimum validation on the flash image file. The utility opens the specified firmware file (*Filename2*), verifies that it is a valid firmware image, performs a series of safety checks, and uses the file to flash the controller with the flash image.

The SAS2Flash Utility completes the following steps to validate the firmware file:

1. Open the firmware file.
2. Check for a valid firmware header signature, as defined by the *Fusion-MPT 2.0 MPI Specification*.
3. Check for zero checksum on the entire firmware image.
4. Determine if the firmware image is valid for the controller being flashed. The utility checks for support in the firmware image for the PCI Device and Revision ID. It checks the PCI Device and Revision ID from the controller’s PCI Config Space with the list of devices supported in the Supported Devices Firmware Extended Image Data.
5. Check for a valid NVDATA Extended Image in the firmware image.
6. Check for NVDATA compatibility.

   The SAS2Flash Utility checks the signature of the CFGI Directory Header and CFGI Product ID structure for validity on the firmware image from the file and on the firmware image from the controller (if the controller already has firmware on it). If this check passes and if the controller already has firmware on it, the utility checks the NVDATA Product ID and NVDATA Vendor ID from NVDATA in the file with the NVDATA from the controller.
7. Verify that the firmware image has a valid INIT image.
8. Verify that the firmware image has a valid BOOTLOADER image.

If any of the validation checks fail, the SAS2Flash Utility sends a failure message to the screen and logs it to the log file.

When the Flash image is successfully downloaded, the SAS2Flash Utility tries to update the firmware version in VPD. It checks the VPD information on Manufacturing Page 1 to determine if valid VPD data is available. If so, and if the VPD data has a keyword to hold the firmware version, the utility updates the version string with the version of the newly downloaded firmware image.

**Syntax:**

```
sas2flash -o -dflash FlashImage.bin FirmwareImage.bin
```
5.4.10  Erase

Use the Erase command, which is available only in the advanced command set, to erase an entire region, as specified by a number.

**CAUTION:** Be sure you want to erase the region before using this command. You cannot undo an erase operation.

**Syntax:**

`sas2flash -o -e 1`

The following table shows the parameters for this command and the region that each parameter erases.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Region to Erase</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NVSRAM</td>
</tr>
<tr>
<td>2</td>
<td>Backup firmware</td>

<td>Boot services</td>
</tr>
<tr>
<td>6</td>
<td>Clean flash (erase everything except manufacturing area)</td>
</tr>
<tr>
<td>7</td>
<td>Erase complete flash</td>
</tr>
<tr>
<td>8</td>
<td>MegaRAID® firmware</td>
</tr>
</tbody>
</table>

5.4.11  Firmware All

Use the Firmware All command to update the firmware on all supported controllers. This command only updates to a later version of firmware image and does not allow the firmware to be downgraded. The update process includes the following steps:

1. Open the specified file.
2. Verify that the file is a valid firmware image, and run through all supported controllers.
   
   The steps for firmware image validation and updating are listed in the description of the **Firmware Update** command.

3. Perform a series of safety checks on each controller, and update the controller if all of the checks are validated. This command relies on the SAS2Flash Utility to determine which controllers need to be updated. Therefore, it is not possible to override any of the safety checks.

4. If any safety check for a given controller fails, skip the controller and continue the process with the next supported controller.

If the firmware download operation succeeds, the SAS2Flash Utility uploads the firmware image and compares it with the downloaded image. If the comparison fails, the utility erases the firmware image and the command fails. If a firmware image is already loaded in the flash memory, it continues to be used, and all firmware update operations download the new firmware image to a backup area.
If both the firmware download operation and the comparison of the uploaded firmware image with the downloaded firmware image are successful, this command issues an adapter reset, which automatically copies the new firmware image from the backup area to the running firmware location.

When the firmware image is successfully downloaded, the SAS2Flash Utility tries to update the firmware version in VPD. It checks the VPD information on Manufacturing Page 1 to determine if valid VPD data is available. If so, and if the VPD data has a keyword to hold the firmware version, the utility updates the version string with the version of the newly downloaded firmware image.

**Syntax:**

```bash
sas2flash –f wall image.fw
```

### 5.4.12 Firmware Update

Use the Firmware Update command to download a new firmware image. This process includes the following operations:

1. Open the specified file.
2. Verify that the file is a valid firmware image, and run through all supported controllers.

The firmware image validation involves the following steps:

a. Check for a valid firmware header signature, as defined by the *Fusion-MPT 2.0 MPI Specification*.

b. Check for zero checksum on the firmware image.

c. Determine if the firmware image is valid for the controller being flashed.

To validate, the SAS2Flash Utility compares the PCI device and revision ID information from the controller's PCI configuration space and from the list of devices in Supported Devices Firmware Extended Image Data.

d. Check for a valid NVDATA Extended Image in the firmware image.

e. Check for NVDATA compatibility. Check the signature of the CFGI Directory Header and CFGI Product ID for validity on the firmware image from the file and on the firmware image from the controller (if the controller already has firmware on it). If the checks pass and the controller already has firmware on it, compare the NVDATA Product ID and NVDATA Vendor ID from the NVDATA from the file with the corresponding IDs from the NVDATA from the controller.

f. Verify that the firmware image has a valid INIT image.

g. Verify that the firmware image has a valid BOOTLOADER image.

h. Determine if NVSRAM is present before allowing Integrated Raid (IR) Firmware flashing. If NVSRAM is not present, do not allow IR Firmware flashing.

i. Determine if Initiator Target firmware is present before allowing IR firmware flashing and vice versa. If it is present, do not allow the firmware update.

3. Perform a series of safety checks on each controller.

4. Display any firmware validation check failures for a given controller on the screen and log them to the log file.

5. Update the controller if it passes all safety checks.

The advanced mode version of this command offers an override if the NVDATA Vendor ID and the NVDATA Product ID fields from the new firmware image do not match the same fields in the firmware that are already flashed on the controller.
If the firmware download operation is successful, the SAS2Flash Utility uploads the firmware image and compares it with the downloaded image. If the comparison fails, the utility erases the image and the command fails. If a firmware image is already loaded in the flash memory, it continues to be used, and all firmware update operations download the new firmware image to a backup area.

If both the firmware download operation and the comparison of the uploaded firmware image with the downloaded firmware image are successful, this command automatically issues an adapter reset, which copies the new firmware image from the backup area to the running firmware location.

When the firmware image is successfully downloaded, the SAS2Flash Utility tries to update the firmware version in VPD. It checks the VPD information on Manufacturing Page 1 to determine if valid VPD data is available. If so, and if the VPD data has a keyword to hold the firmware version, the utility updates the version string with the version of the newly downloaded firmware image.

**Syntax:**

This command is used in both regular mode and advanced mode, with the differences described earlier in this section.

```
sas2flash -f image.fw
sas2flash -o -f image.fw
```

### 5.4.13 Help

Use the Help command to list the command line options that the SAS2Flash Utility recognizes. The `-o` option enables advanced help and allows the display of the advanced option help.

**Syntax:**

```
sas2flash -h
sas2flash -?  
sas2flash -o -h
sas2flash -o -?
```

### 5.4.14 List

Use the List command to list information on the screen about the controller specified in the command. You also can output the information to a log file and pipe it to another destination.

**Syntax:**

```
sas2flash -list
sas2flash -c 2 -list
```

### 5.4.15 List All

Use the List All command to list information on the screen about all controllers supported by the SAS2Flash Utility. You also can output the information to a log file and pipe it to another destination.

**Syntax:**

```
sas2flash -listall
```
5.4.16 List SAS Address

Use the List SAS Address command to list on the screen the SAS address of the specified controller. You also can output the information to a log file and pipe it to another destination.

**Syntax:**

```
sas2flash -o -listsasadd
sas2flash -c 2 -o -listsasadd
```

5.4.17 Log File

Use the Log File command to specify a file for logging output. The SAS2Flash Utility creates the file with the name you specify. If this file name already exists, the utility opens the file and deletes all its contents.

**Syntax:**

```
sas2flash -l logfilename.log
```

5.4.18 Program Assembly

Use the Program Assembly command to program the specified controller with an assembly value. You must provide the complete 16-character assembly value, which is programmed directly to the controller. The value is truncated or padded with termination characters, as required.

**NOTE:** The utility programs the Assembly number and Tracer number directly to Manufacturing Page 0. It programs the SAS Address directly to Manufacturing Page 5.

**Syntax:**

```
sas2flash -o -assem "12AB"
```

5.4.19 Program Board Tracer

Use the Program Board Tracer command to program the specified controller with a board tracer value. When you enter the 16-character value on the command line, the SAS2Flash Utility programs it to the controller. The board tracer value is truncated or padded with termination characters, as needed.

**Syntax:**

```
sas2flash -o -tracer "12AB"
```

5.4.20 Program Ethernet Information

Use the Program Ethernet Information command to program an Ethernet parameter file to the specified controller. You specify the file on the command line. The SAS2Flash Utility then parses the file and programs the data to the appropriate location in nonvolatile storage.

**NOTE:** See Section 9.0, Sample Parameter File for Program Ethernet Information Command, on page 24, for an example of an Ethernet parameter file.

**Syntax:**

```
sas2flash -o -eth ethernet_settings.txt
```
5.4.21 **Program SAS Address**

Use the Program SAS Address command to program the specified controller with a SAS address. You must provide the complete SAS address, which is programmed directly to the controller. This command recognizes the input format of the SAS address. The address can optionally include the hexadecimal prefix 0x.

**Syntax:**

```
sas2flash -o -sasadd 50062b0000000000
sas2flash -o -sasadd 0x50062b0000000000
```

5.4.22 **Program SAS Address High**

Use the Program SAS Address High command to program the specified controller with the first 28 bits (seven characters) of the SAS address, which are specified at the command line. The SAS2Flash Utility then prompts you to enter the other nine characters and programs the value to the controller. Use this command with a barcode reader.

**Syntax:**

```
sas2flash -o -sasaddhi 50062b0
```

5.4.23 **Program VPD**

Use the Program VPD command to program the specified controller with a VPD parameter file. The file name is provided on the command line. The SAS2Flash Utility parses the data in the file you enter on the command line and programs it to the appropriate location in nonvolatile storage. The utility verifies the individual field lengths, but it does not verify the parameter values.

**NOTE:** See Section 8.0, Sample Parameter File for Program VPD Command, on page 23, for an example of a VPD parameter file.

**Syntax:**

```
sas2flash -o -vpd file.vpd
```

5.4.24 **Reset**

Use the Reset command to issue a reset to the specified controller. The command resets the chip hardware and reinitializes all chip information. It also performs the following steps:

- Moves a new firmware image from the firmware backup location to the current firmware location.
- Migrates the NVDATA changes.
- Runs the new firmware.

**Syntax:**

```
sas2flash -o -reset
```
5.4.25  Reset All

Use the Reset All command to issue a reset to all supported controllers in the system. The command resets the chip hardware and reinitializes all chip information. It also performs the following steps:

- Moves a new firmware image from the firmware backup location to the current firmware location.
- Migrates the NVDATA changes.
- Runs the new firmware.

Syntax:

```
sas2flash -o -resetall
```

5.4.26  Scan Character Flag

Use the Scan Character flag to specify a scan character to look for before accepting a SAS address input. You typically use this command to specify the scan character that a barcode scanner sends to indicate the beginning of a valid string. Use the scan character flag only when programming a SAS address. In the command line, the flag must appear before the option to program the SAS address, as shown in the following syntax example.

Syntax:

```
sas2flash -o -scanchar " " -sasadd 50062b0000000000
```

5.4.27  Show Ethernet Information

Use the Show Ethernet Information command to display the contents of the Ethernet pages for the specified controller.

Syntax:

```
sas2flash -o -showeth
```

5.4.28  Show VPD

Use the Show VPD command to display the contents of the VPD file for the specified controller.

Syntax:

```
sas2flash -o -showvpd
```

5.4.29  Silent Switch

Use the Silent switch to enable the silent operation mode, in which the SAS2Flash Utility does not solicit your feedback. The SAS2Flash Utility logs the output to the screen and to a log file, if specified. If an error occurs, the utility does not prompt you for input to correct an error or for your permission to override a safety check.

Syntax:

```
sas2flash -s
```
5.4.30  Test BIOS Version

Use the Test BIOS Version command to test the current BIOS version against a version provided on the command line in the format AA.BB.CC.DD. The SAS2Flash Utility checks all four parts of the version number and outputs the result of the checks through the return codes.

**NOTE:** This command is supported only in the x86 BIOS.

**Syntax:**

```shell
sas2flash -o -testbios 6.08.00.00
```

5.4.31  Test Firmware Version

Use the Test Firmware Version command to test the current firmware version against a version provided on the command line in the format AA.BB.CC.DD. The SAS2Flash Utility checks all four parts of the version number and outputs the result of the checks through the return codes.

**Syntax:**

```shell
sas2flash -o -testfw 1.11.00.00
```

5.4.32  Test Link State

Use the Test Link State command to test the link state of a specific PHY on a specific controller against a provided value. The SAS2Flash Utility outputs the test results through the return codes.

**Syntax:**

```shell
sas2flash -o -testls 4 2
```

**Table 3: Valid Values for Link State Testing**

<table>
<thead>
<tr>
<th>Value</th>
<th>Link State</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Link Down</td>
</tr>
<tr>
<td>1</td>
<td>1.5 Gb/s</td>
</tr>
<tr>
<td>2</td>
<td>3.0 Gb/s</td>
</tr>
<tr>
<td>3</td>
<td>6.0 Gb/s</td>
</tr>
</tbody>
</table>

**Syntax:**

```shell
sas2flash -o -testlsall
```

The valid values for testing the link state follow.

5.4.33  Test Link State All

When you use the Test Link State All command, the utility does not directly test the link state. Instead, it lists the state of all links on the selected adapter. If a PHY does not have a device connected to it, its link state is Link Down.

**Syntax:**

```shell
sas2flash -o -testlsall
```

5.4.34  Test Product ID

Use the Test Product ID command to test the product ID of the current firmware against a product ID provided on the command line in hexadecimal format. The SAS2Flash Utility outputs the test results through the return codes.

**Syntax:**

```shell
sas2flash -o -testprodid 0x2713
```
5.4.35 Test Subsystem Identification

Use the Test Subsystem Identification (SSID) command to input the Subsystem Vendor ID (SSVID) and Subsystem Device ID (SSDID), and to match them to the appropriate PCI information for the selected controller. The output displays any discrepancies in either SSVID or SSDID, or it displays a success message if both values match the selected controller.

**Syntax:**

```
sas2flash -o -testssid 1000:3020
```

5.4.36 Upload BIOS

Use the Upload BIOS command to upload the boot block (BIOS, UEFI, and FCODE) to a file. If the file already exists, the command overwrites it. The command fails if there is not enough free disk space to hold the block. This command is useful in manufacturing environments to perform a comparison after an update.

**Syntax:**

```
sas2flash -ubios image.rom
```

5.4.37 Upload Firmware

Use the Upload Firmware command to upload the current firmware image to a file. If the file already exists, the command overwrites it. The command fails if there is not enough free disk space to hold the firmware image. This command is useful in manufacturing environments to perform a comparison after an update.

**Syntax:**

```
sas2flash -ufirmware image.fw
```

5.4.38 Upload Firmware Backup

Use the Upload Firmware Backup command to upload the firmware backup image to a file. If the file already exists, the command overwrites it. The command fails if there is not enough free disk space to hold the firmware backup image. This command is useful in manufacturing environments to perform a comparison after an update.

**Syntax:**

```
sas2flash -o -ufwbackup image.fw
```

5.4.39 Upload Flash Image

Use the Upload Flash Image command to upload the complete contents of Flash to a file. If the file already exists, the command overwrites it. The command fails if there is not enough free disk space to hold the block. This uploaded image can be used as a master image, with some changes, to program multiple similar controllers.

**Syntax:**

```
sas2flash -o -uflash flash.rom
```

5.4.40 Upload NVDATA

Use the Upload NVDATA command to upload the current binary NVDATA image to a file. If the file already exists, the command overwrites it. The command fails if there is not enough free disk space to hold the binary NVDATA image. This command is useful in manufacturing environments to perform a comparison after an update.

**Syntax:**

```
sas2flash -o -unvdata nvdata.img
```
6.0 Performance

The SAS2Flash Utility runs efficiently and does not cause unnecessary delays. Memory utilization can be as high as 20 MB, depending on the selected operation. The SAS2Flash Utility supports the following exit codes.

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success</td>
</tr>
<tr>
<td>1</td>
<td>Failure</td>
</tr>
</tbody>
</table>

7.0 Operating System Limitations

Some operating systems do not support all SAS2Flash Utility features, because of limitations in their controller interface. If an operating system does not support a command, the utility returns an invalid function code.

The Windows, Linux, and Solaris operating systems do not support commands that require the controller to be taken offline or that require a firmware download of the boot loader. In addition, these operating system cannot flash any part that does not already have valid firmware loaded and running.
8.0 Sample Parameter File for Program VPD Command

This section shows the contents of a sample parameter file for the Program VPD command. Each parameter, or group of parameters, is preceded by a descriptive comment.

;Large Resource Type ID String Tag. Describe the data type.
LR_ID_STRING_TAG = 0x82
;Length of the ID String. Must match the length of the LR_ID_STRING
LR_ID_STRING_LENGTH = 0x001F
;Data. The actual ID String to describe the device this VPD data represents.
LR_ID_STRING = "PCIe2 SAS Adapter Dual-port 6Gb"
;Large Resource Type VPD Tag
LR_VPD_TAG = 0x90
;Total Length of all the VPD keyword, length and data wrapped by a Large
;Resource Type VPD Tag.
LR_VPD_LENGTH = 0x004C
;VPD Keyword. Part Number of Assembly
VPD_KEYWORD = "PN"
VPD_LENGTH = 0x07
VPD_DATA = "45D8028"
;VPD Keyword. Engineering Data Code
VPD_KEYWORD = "EC"
VPD_LENGTH = 0x07
VPD_DATA = "G37068"
;VPD Keyword. CC - Field Service CCIN
VPD_KEYWORD = "CC"
VPD_LENGTH = 0x04
VPD_DATA = "763A"
;VPD Keyword. Reserved and Checksum
VPD_KEYWORD = "RV"
VPD_LENGTH = 0x01
VPD_DATA = "CHECKSUM"
;Small Resource Type End Tag
SR_END_TAG = 0x79
This section shows the contents of a sample parameter file for the Program Ethernet Information command. Each parameter, or group of parameters, is preceded by a descriptive comment.

```
